Multiple Linear Regression

outline:

- setup model & get LS est
  - ↳ matrix formulation of regression
- Gauss-Markov
- Fitted values & estimate σ^2

(1) Model Set Up

SLR: $Y_i = \beta_0 + \beta_1 x_i + \varepsilon_i \quad i = 1, \dots, n$

$$\begin{cases} Y_1 = \beta_0 + \beta_1 x_1 + \varepsilon_1 \\ Y_2 = \beta_0 + \beta_1 x_2 + \varepsilon_2 \\ \vdots \\ Y_n = \beta_0 + \beta_1 x_n + \varepsilon_n \end{cases}$$

Let's define

$$Y = \underset{n\times 1}{\begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_n \end{bmatrix}}, \quad X = \underset{n\times 2}{\begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix}}, \quad \beta = \underset{2\times 1}{\begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix}}, \quad \varepsilon = \underset{n\times 1}{\begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_n \end{bmatrix}}$$

$$Y = X\beta + \varepsilon$$

$$Y = \begin{bmatrix} \beta_0 + \beta_1 x_1 \\ \beta_0 + \beta_1 x_2 \\ \vdots \\ \beta_0 + \beta_1 x_n \end{bmatrix} + \varepsilon$$

← this is equivalent to my system of n equations

Assumptions

$I = \begin{bmatrix} 1 & & 0 \\ & \ddots & \\ 0 & & 1 \end{bmatrix}$

1. X is fixed
2. $\varepsilon \sim N\left(0, \begin{bmatrix} \sigma^2 & 0 & 0 \cdots & 0 \\ 0 & \sigma^2 & & \vdots \\ \vdots & & \ddots & 0 \\ 0 \cdots & & 0 & \sigma^2 \end{bmatrix}\right)$

$$= N(0, \sigma^2 I_n)$$

Aside:

if I have a random vector $Z = \begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix}$

then $E(Z) = \begin{bmatrix} E(Z_1) \\ E(Z_2) \end{bmatrix} = \mu$ is the mean vector

& $Var(Z) = \begin{bmatrix} Var(Z_1) & Cov(Z_1, Z_2) \\ Cov(Z_1, Z_2) & Var(Z_2) \end{bmatrix} = \Sigma$ is the covariance matrix.

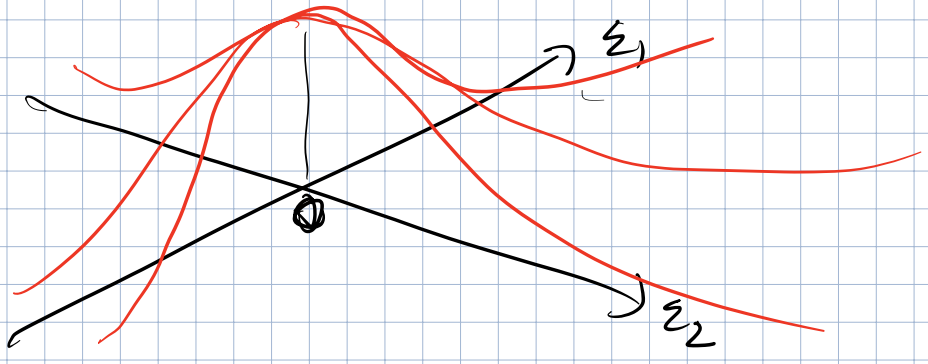
random variable Z: $\mathrm{Var}(Z) = E\left((X-\mu)^2\right)$

random vector Z: $\mathrm{Var}(Z) = E\left((X-\mu)(X-\mu)^T\right)$

$n \times 1$ $\quad$ $1 \times n$

Multivariate Normal Dist

$$\varepsilon = \begin{bmatrix} \varepsilon_1 \\ \vdots \\ \varepsilon_n \end{bmatrix} \sim N(0, \sigma^2 I)$$



$$f(\varepsilon_1, \ldots, \varepsilon_n) = \prod_{i=1}^{n} f(\varepsilon_i)$$

$$= \prod_{i=1}^{n} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\varepsilon_i^2/2\sigma^2}$$

$$= \left(2\pi\sigma^2\right)^{-n/2} e^{-\sum_i \varepsilon_i^2/2\sigma^2}$$

In general a random vector $Z \sim N(\mu, \Sigma)$ has the pdf:

$$f(z_1, \ldots, z_n) = \frac{1}{(\sqrt{2\pi})^n |\Sigma|^{1/2}} e^{-(x-\mu)^T \Sigma^{-1} (x-\mu)/2}$$

---

② Parameter Estimation under Matrix Setup

In SLR the idea was to minimize

$$Q(\beta_0, \beta_1) = \sum_{i=1}^{n} (y_i - \beta_0 - \beta_1 x_i)^2$$

In the matrix setup, we minimize

$$Q(\beta) = (Y - X\beta)^T (Y - X\beta)$$

$$= \| Y - X\beta \|^2$$

If I want to minimize $Q(\beta)$ w.r.t. β which is a vector, we need matrix calculus.

① $\frac{\partial(\beta^T A)}{\partial \beta} = A$

② $\frac{\partial(\beta^T A \beta)}{\partial \beta} = 2A\beta$ if A is symmetric.

③ $\frac{\partial(c)}{\partial \beta} = 0$

$y^T X\beta = \langle y, X\beta \rangle = \langle X\beta, y \rangle$

$= (X\beta)^T y$

$= \beta^T X^T y$

Goal is to Minimize

$Q(\beta) = \|y - X\beta\|^2 = (y - X\beta)^T (y - X\beta)$

$= y^T y - y^T X\beta - (X\beta)^T y + (X\beta)^T (X\beta)$

$= y^T y - y^T X\beta - \beta^T X^T y + \beta^T X^T X \beta$

$-\beta^T X^T y$

$\hookrightarrow \frac{\partial Q}{\partial \beta} = 0 - X^T y - X^T y + 2X^T X\beta \overset{!}{=} 0$

$= -2X^T y + 2X^T X\beta = 0$

$\Rightarrow (X^T X)\beta = X^T y$

$\Rightarrow \hat{\beta} = (X^TX)^{-1}X^TY$ ← the Normal Eq.

(-1) ↙ SLR

$\begin{pmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \end{pmatrix} = \begin{pmatrix} \bar{Y} - \hat{\beta}_1 \bar{X} \\ \frac{SSXY}{SSX} \end{pmatrix}$ [worked out in Cody Notes]

Why did I do this?

Now I can add more predictors to the design matrix, X:

Multiple Linear Regression Model

$$Y_i = \beta_0 + \beta_1 X_{i1} + \cdots + \beta_{p-1} X_{i(p-1)} + \varepsilon_i \qquad i = 1, \ldots, n$$

$$\Downarrow$$

$$Y = X\beta + \varepsilon$$

where

$$X = \underset{n \times p}{\begin{bmatrix} 1 & X_{11} & X_{12} & \cdots & X_{1(p-1)} \\ 1 & X_{21} & X_{22} & & \vdots \\ \vdots & \vdots & \vdots & & \\ 1 & X_{n1} & X_{n2} & \cdots & X_{n(p-1)} \end{bmatrix}} \quad \& \quad \beta = \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_{p-1} \end{pmatrix}$$

So the LS estimate for the MLR model is just $\hat{\beta} = (X^TX)^{-1}X^TY$ (assuming that X has full rank).

Fitted Values

$$\hat{Y} = X\hat{\beta} = X(X^TX)^{-1}X^TY$$

$= H$ = "hat matrix"

$= HY$
